Antimalarial and Antipyretic Activities of Cornsilk Extract and Fractions of Zea Mays

Jude E. Okokon,1 Utibe Bassey,1 John A. Udobang,2 Hemant Kumar Bankehde2

ABSTRACT

To evaluate the antiplasmodial and antipyretic activities of Z. mays L. (Family-Poaceae) cornsilk extract and fractions, to ascertain the folkloric claim of its antimalarial and antipyretic activities. The cornsilk extract (170–510 mg/kg) and fractions (hexane, dichloromethane, ethyl acetate and methanol; 340 mg/kg) were investigated for suppressive, prophylactic, and curative antimalarial activities against chloroquine-sensitive Plasmodium berghei infections in Swiss albino mice and for antipyretic activity against D-amphetamine, 2,4-dinitrophenol and yeast-induced pyrexia. Chloroquine (5 mg/kg) and pyrimethamine (1.2 mg/kg) were used as positive controls for antimalarial models and Acetyl salicylic acid, ASA, (100 mg/kg) was used as standard for antipyretic models. Thin films made from tail blood of each mouse were used to assess the level of parasitaemia of the mice. The extract/fractions progressively reduced parasitaemia induced by chloroquine-sensitive P. berghei infection in prophylactic (46.16–86.80%), suppressive (48.59–71.95%), and curative (22.4–82.34%) models in mice. These reductions were statistically significant (p<0.01–0.001). They also improved significantly (p<0.01–0.001) the mean survival time (MST) from 18.91 to 23.66 d in suppressive, 17.33 to 28.00 in prophylactic and 20.25 to 26.75 d in curative models relative to control (13.75 d). The activities of extract/fractions were comparable to that of the standard drugs used (pyrimethamine) in prophylactic model only. The extract exerted prominent inhibition of pyrexia on amphetamine, dinitrophenol and yeast-induced pyrexia (5 h). Inhibition was significant (p<0.05–0.001) from 2 to 5 h post-administration of extract and in a dose-dependent fashion. The plant may possess antimalarial and antipyretic effects which may in part be mediated through the chemical constituents of the plant.

Keywords: Zea mays, cornsilk, antimalarial, antipyretic, antimalplasmodial activity,9 anti-fatigue,10 anti-depressant activity,11 anti-hyperlipidemic activity,12 anti-diabetic effects.13,14 Anti-inflammatory activity,15 Antioxidant,16,17,18,19 anticancer,20 α-amylase inhibitory,21 antidiabetic and hypolipidemic activities.22,23 We report in this study the antimalarial and antipyretic activities of the cornsilk extract and fractions of Zea mays.

INTRODUCTION

Zea mays L. (Poaceae) also known as maize or corn, is an annual grass plant cultivated through Nigeria primarily for human consumption and as animal feed. The plant is tall with a fibrous root system and has long narrow leaves on opposite side of the stem and bears ears that are enclosed in modified leaves known as husks.1 Besides its nutritive values, maize grains, leaves, cornsilks, stalk, and inflorescence are also used in ethnomedicine for the treatment of several ailments. The corn silk is used as an antidiabetic or diuretic, and decoction of the silk is consumed for the treatment of urinary troubles and gallstones.2 Corn silk was used in many parts of the world for the treatment of cystitis, gout, kidney stones, malaria, prostate hypertrophy, nephritis and heart disorders.3 Secondary metabolites like flavonoids, saponins, alkaloids, tannins, chlorogenic acid, allantoin, and phytosterols as well as flavonoids such as maysin, apig-maysin, 3-methoxymaysine and ax-4-OH-maysin have also been identified from corn silk.4 Biological activities include; antioxidative stress,5,6 a and kaliuresis effect,7 hyperglycemic effect,8 nephroprotective activity,9 anti-fatigue,10 anti-depressant activity,11 anti-hyperlipidemic activity,12 anti-diabetic effects.13,14 Anti-inflammatory activity,15 Antioxidant,16,17,18,19 anticancer,20 α-amylase inhibitory,21 antidiabetic and hypolipidemic activities.22,23 We report in this study the antimalarial and antipyretic activities of the cornsilk extract and fractions of Zea mays.

MATERIALS AND METHODS

Collection and identification of plant material

The cornsilk extract of Zea mays L. (Family-Poaceae) were collected from farms in the Uyo area of Akwa Ibom State, Nigeria in May, 2018. The plant was identified by a taxonomist in the Department of Botany and Ecological Studies, University of Uyo, Uyo, Nigeria. A voucher specimen of the plant (FPH, 614) was deposited in the Faculty of Pharmacy’s herbarium at the University of Uyo.

Extraction

The cornsilk were washed and shade dried for two weeks. The dried cornsilk were pulverized...
to powder using an electric grinder. The powdered cornsilk were divided into two parts (1.5 kg each). One part was macerated in ethanol for 72 hours, while the remaining part was successively and gradiently macerated for 72 hours in each of, n-hexane, dichloromethane, ethyl acetate and n-butanol respectively, which is along their polarity to give the corresponding gradient extract for each solvent. The liquid filtrate of each extract and fraction was concentrated and evaporated to dryness in vacuo at 40°C using a rotary evaporator. The extract and fraction were stored in a refrigerator at -4°C, until used for the proposed experiments.

Microorganism (parasite)
Chloroquine-sensitive strain of *Plasmodium berghei berghei* were obtained from the National Institute of Medical Research (NIMER), Yaba Lagos, Nigeria and maintained by subpassage in mice.

Parasite inoculation
Each mice used in the experiment were inoculated intraperitoneally with 0.2 mL of infected blood containing about 1 x 10⁷ *P. berghei berghei* parasitized erythrocytes. The inoculum consisted of 5 x 10⁷ *P. berghei berghei* erythrocytes per milliliter. This was prepared by determining both the percentage parasitemia and the erythrocytes count of the donor mouse and diluting the blood with isotonic saline in proportions indicated by both determinations.

Experimental animals
Male and female Swiss albino rats (125-150 g) and mice, (18-25 g), were obtained from the University of Uyo animal house. They were kept in standard cages and acclimatized for a period of 10 days before use in the experiments. The mice were fed on standard pellet diet and water *ad libitum*. All animals were kept at room temperature in cross ventilated rooms. The care and use of animals were conducted in accordance with the National Institute of Health Guide for the Care and Use of Laboratory Animals (NIH Publication, 1996). Approval for the study was obtained from the University of Uyo’s Animal Ethics Committee.

Determination of median lethal dose (*LD₅₀*)
The median lethal dose (*LD₅₀*) of the extract was estimated using albino mice by intraperitoneal (i.p) route using the method of Lorké as reported by Okokon et al. This involved intraperitoneal administration of different doses of the extract (100– 1000 mg/kg) to groups of three mice each. The animals were observed for manifestation of physical signs of toxicity such as writhing, decreased motor activity, decreased body/limb tone, and decreased respiration and death. The number of deaths in each group within 24 h was recorded. The *LD₅₀* value was calculated as the geometrical means of the maximum dose producing 0% (a) and the minimum dose producing 100% mortality (b). *LD₅₀ = √ (ab)*

Drug administration
The extract, fractions, chloroquine and pyrimethamine that were used in the study were administered orally with the aid of a stainless metallic feeding cannula.

Evaluation of the in vivo antimalarial activities of cornsilk extract and fractions of *Zea mays*:
*Evaluation of suppressive activities of the cornsilk extract and fractions of *Zea mays* (4-day test)*
This test was used to evaluate the schizontocidal activity of the crude extract and fractions as well as chloroquine against early *P. berghei berghei* infection in mice. This was done using the method of Knight and Peters as described by Okokon et al. Fifty-four mice were randomly divided into nine groups of six mice each. On the first day (D₀), the fifty-four mice were infected with the parasite and randomly divided into various groups. These were administered the crude extract, fractions, chloroquine and distilled water. The mice in group 1-3 were given 170 mg/kg, 340 mg/kg and 510 mg/kg of crude extract respectively, while groups 4, 5, 6, 7 were administered 340 mg/kg of n-hexane, dichloromethane, ethyl acetate and n-butanol fractions respectively, group 8 was given 5 mg/kg of chloroquine (positive control) and group 9 given 10 mL/kg of distilled water (negative control) for four consecutive days (D₀-D₄) between 8am to 9am. On the fifth day (D₅), thin films were made from the tail blood. The films were stained with Giemsa stain to reveal parasitized erythrocytes out of 500 in a random field of the microscope. The average suppression of parasitemia was calculated as follows: (average % parasitemia positive control – average % parasitemia negative control) / (average % parasitemia negative control).

The mean survival time of the mice in each treatment group was determined over a period of 29 days (D₀-D₂₉), as follows:
(No. of days survived) / (total No. of days (29) × 100)

*Evaluation of prophylactic or repository activities of the cornsilk extract and fractions of *Zea mays**
This was evaluated using the method of Peters as described by Imoh et al. The mice were randomly divided into nine groups of six mice...
were given 170, 340, and 510 mg/kg of crude extract respectively, groups 4, 5, 6, and 7 were given 340 mg/kg of n-hexane, ethyl acetate, dichloromethane, and n-butanol fractions respectively, group 8 was given 1.2 mg/kg of pyrimethamine (positive control) and group 9 given 10 mL/kg of distilled water (negative control). Administration of the extract and fractions continued for three consecutive days ($D_0$-$D_2$). On the fourth day ($D_3$), the mice were inoculated with *P. berghei berghei*. The parasitemia level was assessed by blood smears 72 hours later. The mean survival time of the animals were calculated over a period of 29 days.

**Evaluation of the curative activities of the cornsilk extract and fractions of Zea mays**

This test was used to evaluate the schizontocidal activity of the extract, fractions and chloroquine in established plasmodial infection. This was conducted according to the method of Ryley and Peters as described by Okokon et al. *P. berghei berghei* was injected intraperitoneally into another fifty four mice on the first day ($D_0$). Seventy two hours later ($D_1$), the mice were divided into nine groups of six mice per group. Groups 1-3 were given different doses of extract, 170, 340, and 510 mg/kg respectively, groups 4-7 were given 340 mg/kg of n-hexane, ethyl acetate, dichloromethane, and n-butanol fractions respectively, group 8 was given 5 mg/kg chloroquine (positive control) and group 9 was given 10 mL/kg distilled water (negative control). The crude extract, fractions and chloroquine were administered once daily for 5 days. Giemsa stained thin smears were prepared from tail blood samples collected on each day of treatment to monitor the parasitemia level. The mean survival time (MST) of the mice in each group was determined over a period of 29 days ($D_0$-$D_{28}$).

**Evaluation of antipyretic activity**

**Evaluation of antipyretic activity of the cornsilk extract on D-amphetamine-induced pyrexia**

Adult albino rats (130 – 150 g) of both sexes fasted for 24 hours but allowed water *ad libitum* were used for the experiment. They were randomized into groups of six rats each. DNP (10 mg/kg, i.p.) was administered to the rats after obtaining the basal rectal temperatures. Hyperthermia developed within 30 min of DNP administration. Different doses of extract (170, 340, and 510 mg/kg i.p.), aspirin (100 mg/kg), and distilled water (10 mL/kg, orally) were administered to the treatment and control groups of animals. Rectal temperatures of the animals were obtained at 1 h intervals for 5 h.

**Effect of cornsilk extract on 2,4-Dinitrophenol (DNP)-induced pyrexia**

Adult albino rats of both sexes fasted for 24 h but allowed water *ad libitum* were used for the experiment. They were randomized into groups of six rats each. DNP (10 mg/kg, i.p.) was administered to the rats after obtaining the basal rectal temperatures. Hyperthermia developed within 30 min of DNP administration. Different doses of extract (170, 340, and 510 mg/kg i.p.), aspirin (100 mg/kg), and distilled water (10 mL/kg, orally) were administered to the treatment and control groups of animals. Rectal temperatures of the animals were obtained at 1 h intervals for 5 h.

**Statistical analysis**

Data obtained from this work were analyzed statistically using ANOVA (One-way) followed by a post test (Turkey-Kramer multiple comparison test). Differences between means were considered significant at 5% level of significance, that is $p \leq 0.05$.

**RESULTS**

**Determination of median lethal dose (LD$_{50}$)**

The median lethal dose (LD$_{50}$) value was calculated to be 1732.05 mg/kg. The physical signs of toxicity included excitation, paw licking, increased respiratory rate, decreased motor activity, gasping, convulsion and coma which was followed by death.
Suppressive activities of ethanol cornsilk extract and fractions of *Z. mays*

The extract and its fractions exerted dose-dependent reductions in parasitaemia of the treated mice in various groups. These reductions were statistically significant relative to the control (*p*<0.001). The methanol fraction demonstrated the highest suppressive activity (71.95%) and m.s.t value of 22.66 d although less than that of the standard, Chloroquine, 5 mg/kg (94.02%) (Table 1).

### Prophylactic/repository activities of ethanol cornsilk extract and fractions of Z. mays

The ethanol cornsilk extract showed dose-dependent reductions of parasitaemia in the extract-treated groups. These reductions were statistically significant relative to the control ($p<0.01–0.001$). The methanol fraction showed the most prominent prophylactic activity (86.80%) and m.s.t value of 26.66 d which was significant ($p<0.001$) when compared with control but was comparable to that exhibited by the standard drug, pyrimethamine, 1.2 mg/kg (Table 2).

### Antiplasmodial effect of ethanol cornsilk extract and fractions of Z. mays on established infection

There were progressive dose-dependent reductions of parasitaemia in all the extract/fraction-treated
groups relative to control. These reductions were statistically significant relative to the control ($p<0.001$; Figure 1). The methanol fraction had the highest activity with chemosuppressive effect of 84.93%, this was lower compared with that of the standard, chloroquine, 100%.

The cornsilk extract and fractions demonstrated significant ($p<0.05-0.001$) protective potentials on the mice as was seen in the mean survival time of the animals. The groups treated with ethyl acetate fraction had a longer mean survival time, 26.75 ± 1.97 d followed by those of methanol fraction treated mice, 22.75 ± 0.75 d. These were less than that of the standard drug, chloroquine (30.00 ± 0.00 d; Table 3).

**Effect of ethanol cornsilk extract on D-amphetamine induced pyrexia**

The antipyretic effect of the extract on amphetamine-induced pyrexia is shown in Table 4. Cornsilk extract (170-510 mg/kg), in the presence of the pyrogen, caused significant ($p<0.05$ – 0.001) reductions in the temperatures of the extract-treated rats when compared with the control. These effects were pronounced at the 4 h and 5 h post treatment with the extract. The antipyretic effects of the extract were comparable with that of the standard drug, ASA,100 mg/kg (Table 4).

**Effect of ethanol cornsilk extract on 2,4-dinitro nitrophenol (DNP)-induced pyrexia in rats**

The cornsilk extract (170-510 mg/kg) demonstrated significant ($p<0.05-0.001$) dose-dependent lowering of temperature in DNP-induced pyretic rats. The antipyretic effect was, however, pronounced ($p<0.05-0.001$) at the 5 h in all the extract-treated groups. The effect of the highest dose (510 mg/kg) was comparable to that of the standard drug, ASA, 100 mg/kg (Table 5).

**Effect of cornsilk extract of on yeast-induced pyrexia in rats**

Ethanol cornsilk extract of *Z. mays* (170-510 mg/kg) caused significant ($p>0.05$-0.001) reduction of rat body temperature of rats elevated by the administration of yeast. The effect of the extract was pronounced at the 5 h. The antipyretic effects of the extract was not comparable to that of the standard, ASA,100 mg/kg (Table 6).

**DISCUSSION**

The cornsilk tea is used traditionally by the Ibibios of Southern Nigeria and other parts of the world as a malarial remedy and febrifuge. This work was designed to evaluate the antimalarial and antipyretic activities of the cornsilk extract and fractions of *Zea mays*. The median lethal dose (LD$_{50}$) value was calculated to be 1732.05 mg/kg which shows that the cornsilk extract is slightly toxic. The antimalarial activity of the cornsilk extract and fractions was evaluated against rodent malaria parasite, *Plasmodium berghei* infection in mice using standard in vivo models. The extract and fractions were found to significantly reduced parasitemia in suppressive, prophylactic and curative models in a dose-dependent fashion with the methanol fraction exerting the highest antimalarial activity. The extract and fractions also prolonged the MST of the mice considerably suggesting that they were potentially able to offer significant degree of protection to the mice. This activity could have resulted from plasmodicidal or plasmodistatic activity of the extract and fractions.

The observation that the extract and fractions showed considerable in vivo activity suggest also the involvement of antioxidant activity which maybe due to the activities of phytochemical compounds present in the cornsilk extract and fractions.

Besides, the cornsilk fractions have been observed in this study to exhibit pronounced antioxidant activity, and the cornsilk extract has been known to be rich in flavonoids which are known for significant antioxidant activity. Antioxidant potentials of some plant and natural products especially flavonoids have been found to promote schizonticidal activity by modulating the cellular signalling pathway and this has been suggested to be responsible for antiplasmodial activity of compounds such as quercetin as elevated free radicals levels which are common features of malaria disease are implicated in severe malaria complications. This also could be one of the modes of action of this extract as it contains phenolics and flavonoids with antioxidant activity. Moreover, flavones glycosides with antioxidative activity have been reported in cornsilk extract, which further confirms the antioxidative potentials. These may in part contribute to the strong antimalarial and antioxidant activities of the cornsilk extract.

Other mechanisms of antiplasmodial activity have been proposed for flavonoids besides antioxidant activity. Flavonoids are known to exert antiplasmodial activity by chelating with nucleic acid base pairing of the parasite, thereby producing plasmodicidal effect. Other modes of action include modulation of host immunity to tackle disease and inhibition of plasmodial enoyl-ACP reductase (FAB I enzyme)—a key regulator of type II fatty synthases (FAS-II) in *P. falciparum*. Flavonoids may also bind the parasite’s serinethreonine kinase with high affinity and affect its development. These compounds (flavonoids) present in this plant extract and in particular the methanol fraction may...
in part have contributed to the plasmocidal activity of this extract/fraction and therefore explained the mechanism of antiplasmodial effect of the extract.

On antipyretic activity, the extract inhibited significantly amphetamine, dinitrophenol and yeast-induced pyrexia. The cornsilk extract (170-510 mg/kg) showed considerable dose-dependent reduction in the elevated temperatures of the extract-treated rats in the three models (amphetamine, DNP and yeast-induced pyrexia) evaluated. The antipyretic effect was sustained throughout the duration of the work with the effect being quite comparable to ASA (100 mg/kg). Pyrexia (fever) is the body’s response to tissue damage, inflammation, malignancy or graft rejection that results in the formation of large amounts of cytokines, interleukin, interferon and TNF-α, and increasing PGE2 to trigger the hypothalamus and then cause fever.

In the brain, amphetamine causes the release of biogenic amines that are stored in nerve terminals leading to increases in the cAMP level, resulting in prostaglandins synthesis from arachidonic acids in neurons through hydrolysis of phospholipids. This results in hyperthermia.44 DNP causes hyperthermia by uncoupling oxidative phosphorylation resulting in calcium release from mitochondrial stores and preventing calcium reuptake. This leads to increased intracellular calcium level, muscle contraction and hyperthermia.45 The extract through its components may have caused stimulation of the sarcoplasmic reticulum Ca2+-ATPase thus promoting calcium reuptake into the sarcoplasmic reticulum, muscle contraction and hypothermia.46 Yeast induced pyrexia which is pathogenic and caused by PGE2 production, which then resets the thermoregulatory center in the hypothalamus to a higher level.47 Antipyretics lower elevated body temperature by suppressing cyclooxygenase actions and decreasing PGE2 levels in the hypothalamus.48 Temperature regulation involves a delicate balance between heat production and loss, and the hypothalamic thermostat.49 Cyclooxygenase (COX2) activity leads to the synthesis of PGE2 which is an imperative mediator of fever within the hypothalamus and most NSAIDs antipyretic activity results from suppression of prostaglandin synthetase in the hypothalamus. The resultant antipyretic effects could be due to reduced PGE2 levels in the hypothalamus acting on COX2, or through increased production of substances such as vasopressin and arginine that reduce temperature.49 Another possible antipyretic mechanism of the extract is the mediation of the vasodilation of superficial blood vessels which causes improved heat loss from resetting of hypothalamic thermostat.49 The extract may have caused hypothermia by acting through any of these mechanisms.

Flavonoids such as baicalin exhibit antipyretic activity by inhibiting tumour necrosis factor,50 and related compounds also suppress arachidonic acid peroxidation, resulting in decreased prostaglandin levels and fever reduction.51 The phytochemical constituents of this extract which include flavonoids and other phenolic compounds4 may be responsible for its antipyretic effect through any or all mechanisms described here.

The results of this study demonstrated that cornsilk extract of Zea mays possibly possesses considerable antiplasmodial and antipyretic properties. These confirm its use to treat malaria and fever in folkloric medicine. Therefore, it would be interesting if the active principle is isolated, identified, and characterized.

CONFLICT OF INTEREST STATEMENT
The authors declare that they have no conflict of interest.

ACKNOWLEDGEMENTS
The authors are grateful to Mr. Nsikan Malachy of Pharmacology and Toxicology Department for his technical assistance.
